Decreasing mortality with drotrecogin alfa in high risk septic patients
A meta-analysis of randomized trials in adult patients with multiple organ failure and mortality >40%

ABSTRACT
Objective. Sepsis is a complex inflammatory disease, rising in response to infection. Drotrecogin alfa, approved in 2001 for severe sepsis, has been withdrawn from the market. The aim of this study was to assess if drotrecogin alfa-activated can reduce mortality in the more severe septic patients.

Methods. We searched PubMed, Embase, Scopus, BioMedCentral, and in Clinicaltrials.gov databases to identify every randomized study performed on drotrecogin alfa-activated in any clinical setting in humans, without restrictions on dose or time of administration. Our primary end-point was mortality rate in high risk patients. Secondary endpoints were mortality in all patients, in patients with an Acute Physiology and Chronic Health Evaluation (APACHE) 2 score ≥25 and in those with an APACHE 2 score ≤25.

Results. Five trials were identified and included in the analysis. They randomized 3196 patients to drotrecogin alfa and 3111 to the control group. Drotrecogin alfa was associated with a reduction in mortality (99/263 [37.6%] vs 115/244 [47.1%], risk ratios (RR) = 0.80[0.65; 0.98], p = 0.03) in patients with multiple organ failure and a mortality risk in the control group of >40%, but not in the overall population or in lower risk populations.

Conclusions. In high risk populations of patients with multiple organ failure and a mortality of >40% in the control group, Drotrecogin alfa may still have a role as a lifesaving treatment. No beneficial effect in low risk patients was found. An individual patient meta-analysis including all randomized controlled trial on sepsis is warranted, along with new studies on similar drugs such as protein C zymogen.

Key words: sepsis, shock, intensive care, critically ill, mortality, drotrecogin alfa, recombinant human activated protein C

Introduction
Sepsis is a complex systemic inflammatory syndrome rising in response to severe infection, and is a leading cause of mortality and morbidity worldwide. Eighteen million sepsis cases have been estimated to occur each year, with a mortality rate of nearly 30%. (1) Sepsis is a multifaceted syndrome involving endothelial dysfunction, inflammatory response, immunity, deregulation of intercellular signaling, and cytokine storms. (2,3) Sepsis is classified as severe when organ dysfunction ensues. Recombinant human activated protein C (drotrecogin alfa-activated) was approved in 2001 by FDA for severe septic patients at high risk of death, with an Acute Physiology and Chronic Health Evaluation (APACHE) II score higher than 25, while the European marketing authorization was guaranteed for patients with severe sepsis and two or more organ failures. Recently, the drug was voluntarily withdrawn from the market by the pharmaceutical company, in response to the findings of a large
randomized trial that questioned its risk/benefit ratio in patients with septic shock. (4) Protein C is the plasmatic zymogen, and it is activated in the presence of thrombin - thrombomodulin complex, thus limiting thrombin production (through inactivation of factors Va and VIIIa) while also promoting fibrinolysis. Moreover, it may inhibit cytokine production, neutrophil activation and leukocyte adhesion. (5–8) Protein C shares the same benefits of its activated form (drotrecogin alfa) in septic shock, where it exerts a complex role between immunity, coagulation and inflammation. Protein C seems safer than drotrecogin alfa, with no reported increase in bleeding episodes. However high quality randomized evidence on Protein C is lacking. The finding of a significant positive effect of drotrecogin alfa on patients’ mortality could be relevant even if the drug is not commercialized anymore, as a similar but safer and much less studied drug exists: Protein C.

We therefore performed a meta-analysis of randomized control trials (RCTs) to assess if drotrecogin alfa-activated can reduce mortality in the more severe septic patients, defined as those with multiple organ failure and a high mortality rate (> 40%).

Materials and methods
Search Strategy
We searched PubMed, Embase, Scopus, BioMedCentral, and the Clinicaltrials.gov database (updated September 1st 2012) for relevant studies. Search was independently conducted by four trained investigators. The search strategy (9) included any randomized study ever performed on drotrecogin alfa-activated (Xigris®; Eli Lilly and Company, Indianapolis, IN, USA) in any clinical setting in humans, and is available in the Appendix. Moreover, pertinent references of retrieved articles and reviews were retrieved to identify more articles. No language restriction was enforced.

Study Selection
Results from database and literature queries were first independently examined at a title/abstract level by the four investigators, with divergences resolved by consensus. Pertinent articles were retrieved as full text and analyzed adopting the following inclusion criteria: random allocation to treatment and comparison of drotrecogin alfa-activated versus control. There were no restrictions on dose or time of administration.

The exclusion criteria were: duplicate data, and non-adult studies. Two investigators independently assessed compliance with selection criteria and selected studies for the final analysis, with divergences finally resolved by consensus.

Data Abstraction and Study Characteristics
Two authors extracted study end-points and main outcomes, study design, population, clinical setting, and treatment duration. The primary end-point of the present investigation was the mortality rate in high risk patients, identified as having multiple organ dysfunction, and a high mortality rate in controls. A 40% mortality rate was arbitrarily chosen as the cut-off to define high mortality rate. Secondary endpoints were mortality in all patients, mortality in patients with an APACHE 2 score ≥ 25 and in those with an APACHE 2 score ≤ 25.

Internal Validity and Risk of Bias Assessment
The internal validity and risk of bias of included trials was appraised by two independent reviewers according to Cochrane Collaboration methods, (10) with divergences resolved by consensus. Publication bias was assessed by visual inspection of funnel plots.

Data Analysis and Synthesis
Computations were performed with RevMan 5. (11) Statistical heterogeneity and inconsistency were measured using I². Binary outcomes from individual studies were analyzed in order to compute individual and pooled risk ratios (RR) with pertinent 95% confidence intervals (CI, with equivalence set at 1, odds ratio (OR) < 1 favoring the first treatment, and OR > 1 favoring the second treatment), by means of Mantel-Haenszel method and with random effect model (to better account for clinical and statistical variations). No continuous variables were included in analyses.

Statistical significance was set at the two-tailed 0.05 level for hypothesis testing and at 0.10 for heterogeneity testing. Unadjusted P values are reported throughout. This study was performed in compliance with The Cochrane Collaboration and PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. (12)

Results
Database searches and scanning of article bibliographies yielded a total of 214 results. Excluding 188 non-pertinent titles or abstracts, we retrieved in complete form, and assessed according to the selection criteria, 16 studies (figure 1). Six studies were further excluded because they were not randomized. (1,13–17) Two studies were excluded because they involved a pediatric setting. (18,19) Two were further excluded because they were conducted in other settings, like pancreatitis and pulmonary embolism. (20,21) One was excluded due to the administration of a study drug in controls. (22) Ultimately, therefore, we identified 5 eligible randomized clinical trials for inclusion in the analysis. (4,8,23–25)

Study Characteristics
The 5 included trials randomized 6307 patients (3196 to drotrecogin alfa and 3111 to the control group) (table 1). All these studies reported data on mortality and were multicentre. Study quality appraisal indicated that studies were of variable quality (table 2) and that 3 of them had low risk of bias.

Quantitative Data Synthesis
Drotrecogin alfa was associated with a reduction in mortality (99/263 [37.6%] vs 115/244 [47.1%], RR=0.80[0.65; 0.98], p for effect=0.03, p for heterogeneity=0.77, I²=0% with 507 patients and two studies included) (4,23) (figure 2) in high risk patients, but not in the overall population or in other populations at lower risk (table 3). A trend was noted towards an excess in mortality in
the treatment group when low risk patients were considered (table 3). Visual inspection of funnel plots did not identify a skewed or asymmetrical shape for mortality.

**Discussion**

The most important result of this study is that drotrecogin alfa reduces mortality in high risk septic patients (identified in this study as those with multiple organ failure and mortality in the control group higher than 40%). While another systematic review (26) on the effects of drotrecogin alfa included randomized and non randomized studies, this meta-analysis was based solely on high quality randomized controlled trials. The present study also confirms that drotrecogin alfa does not reduce mortality in the overall population of septic patients, as previously described. (23,27) Moreover, in low risk patients with an APACHE II score ≤ 25, no significantly higher risk of death was found. This finding is reassuring when confronted with the increased risk for severe complications (bleeding) described in the ADDRESS study.

The Prospective Recombinant Human Activated Protein C Worldwide Evaluation in Severe Sepsis (PROWESS) trial (23) and its following subgroup analyses (28,29) found a consistent reduction in mortality in patients at higher risk of death, as defined by multi-organ failure or APACHE II scores higher than 25. Early enthusiasm left room for a more cautious interpretation after publication of the Administration of drotrecogin Alfa (Activated) in Early Stage Severe Sepsis (ADDRESS) trial, (24,30) conducted on patients with severe sepsis and low risk of death. This trial was terminated earlier for safety concerns by the monitoring committee. No difference was shown on 28th day or in-hospital mortality between drotrecogin alfa and placebo, while an increase in serious bleeding in the drotrecogin alfa group was detected.

The subsequent PROWESS-SHOCK trial was recently published by Ranieri et al. (4) This multicenter randomized controlled trial was conducted to test the hypothesis that drotrecogin alfa could reduce mortality in patients with septic shock. This population of patients was identified from the previous published trials as potentially benefiting from protein C activated. However, no significant reduction in mortality was found at 28 days (26.4% in drotrecogin alfa vs 20.8% in placebo).
gin alfa group vs 24.2% in controls, p=0.31) or 90 days (34.1% in drotreco-
gin alfa group vs 32.7% in controls), nor in subgroups of patients defined by
organ failure or APACHE II scores.
Drotrecogin alfa was on the market
for ten years before being withdrawn.
In this decade sepsis treatment has
dramatically improved, with the deve-
lopment of new therapeutic strategies:
the introduction of sepsis bundles, (31)
including early goal directed therapy,
(32) the use of protective lung ventila-
tion, (33) and other interventions which
have been more recently questioned,
like glycemic control (34) and cortico-
steroid therapy. (35)
These new strategies have reduced
mortality up to 50% (36,37) in septic
patients, a finding confirmed in recent
trials. (38–40) For this reason the com-
parison of earlier studies on drotrecogin
alfa with more recent studies may be
misleading, due to the differences in
treatment. The consistent beneficial
effect of drotrecogin alfa on mortality
was indeed clearly demonstrated only
in the first studies (PROWESS), when
mortality in the standard treatment
group was around 40%.
The APACHE II score was developed
by Knaus et al. (41) to graduate criti-
cally ill patients’ prognosis. However,
with improvement in sepsis treatment,
the reliability of APACHE II scores in
predicting mortality is reduced or at
least modified compared with studies
published several years ago. Conseque-
tently, to reduce confounding due to
higher survival rate in more recent studi-
es, in this study we defined a subgroup
of very high risk patients. We consi-
dered not only the APACHE 2 score
or the number of organs involved, but
we adopted the control group mortality
rate as a stable index of poor prognosis
among decades. Despite the secular
trend of improved survival, in this popu-
lation of high risk patients drotrecogin
alfa treatment was associated with a
significant reduction in mortality.
The new therapeutic strategies for
sepsis focus on timely interventions in
order to limit decline of organ function.
Early intervention limits the subse-
quently cascade of endothelial and cellular
dysfunction that leads to an ominous
prognosis. Drotrecogin alfa (activated)
may still be beneficial, thanks to its pro-
fibrinolytic anti-inflammatory action, in
patients with very poor prognosis where
both full blown endothelial dysfunction
and compromise of inflammatory and
coagulation cascade are present.
The PROWESS-SHOCK (4) showed the
same trend in mortality in this high risk
subpopulation of patients (RR 0.83 [95%
CI 0.6-1.14]), but was underpowered to
reach statistical significance. Moreover,
no increase in serious bleeding was
detected (p=0.81), a reassuring finding
that counterbalance the results of Abra-
ham et al. (24)
Our results are consistent with those
from Kalil et al. that found a benefi-
cial effect of drotrecogin alfa in septic
patients through a meta-analysis that
included high and low quality studies,
like case series and non-randomized
controlled trial and reporting drotreco-
gin effect on the overall population of
septic patients. (42)
Given these results, even if drotreco-
gin alfa has been withdrawn from the
market, the commercial availability of
its twin molecule Protein C zymogen is
an exciting alternative. (43-45) High risk
septic patients may still benefit from
protein C action, and while further anal-
ysis should be conducted on drotreco-
gin alfa, at least with an individual
patient meta-analysis, the effect of Pro-
tein C zymogen should be evaluated in
further trials.
Limitations
The limitations of this study are those
specifically related to meta-analysis,
including suboptimal quality of the
included studies. Moreover, in this

Figure 1. Flow diagram for selection of articles.

Figure 2. Forest plot for the risk of mortality in very high risk patients.
study we identified high risk patients through an ex-post analysis that identified the highest risk patient despite improved patient prognosis. A cut-off of 40% mortality was arbitrarily chosen to identify this high risk population of patients despite the secular trend of improved survival. As this population of patients was identified by an ex-post analysis, it cannot be translated as is in the clinical setting without the development of new predictive scores.

**Conclusion**

In high risk patients with multiple organ failure and high mortality rate in the control group, drotrecogin alfa may still have a role as a life saving treatment. No beneficial effect in lower risk patients was found. Since no new large RCT will probably be conducted on this drug, now withdrawn from the market, an individual patient meta-analysis including all randomized controlled trials on sepsis is warranted, along with new studies on similar drugs such as protein C zymogen.
